ABSTRACT

Aims: To determine the rate of weight loss and the relationship between weight loss, length of hospital stay, and treatment response in pneumonia patients aged 6-60 months treated at Children's Hospital 2 (CH2).

Methods: A hospital cross-based prospective study was conducted on 208 patients aged 6-60 months diagnosed with pneumonia and treated as inpatients at the Respiratory Department 1 and 2 of CH2 from March to April 2024.

Results: The rates of weight loss after 3 days, after 7 days of hospitalization, and at discharge were 27.6%, 38.1%, and 38.0% respectively. The length of hospital stay for children with weight loss ≥ 5% after 3 days of hospitalization and at discharge was longer than for those with weight loss < 5%, and this difference was statistically significant (p < 0.05). Children with weight loss ≥ 5% after 3 days of hospitalization and at discharge had a poorer treatment response compared to children with weight loss < 5% [(RR (95%CI)= 5.88 (1.71-20.1) and RR (95%CI)= 4.86 (1.95-12.1), respectively (p=0.025 and p=0.001).

Conclusions: Regularly monitoring children's weight during treatment and providing nutritional support to prevent excessive weight loss is essential to improve the treatment process and the hospital stay.

Keywords: pneumonia, weight loss, length of hospital stay, treatment response.

I. INTRODUCTION

Weight loss in children is a serious issue that affects their overall development and health. Sick children may experience weight loss due to reduced appetite or decreased ability to eat, combined with increased metabolic demands. Rapid weight loss negatively impacts treatment and requires timely assessment and intervention. This can lead to nutritional complications and reduced treatment efficacy, resulting in increased morbidity rates, longer hospital stays, higher treatment costs, and diminished quality of life [1,2,3]. Currently, there is limited research on weight loss in hospitalized children and its relationship to treatment response. Therefore, the study aimed to investigate the relationship between weight loss after 3 days, after 7 days of hospitalization, at discharge with the length of hospital stay and treatment response.

II. METHODS

Study design

A hospital-based prospective was carried out between March and April, 2024 on patients aged 6 – 60 months diagnosed with pneumonia and treated as inpatients at the Respiratory Departments 1 and 2, Children's Hospital 2. Pneumonia patients are diagnosed according to the protocol and admitted based on the hospital's admission criteria.

Inclusion Criteria

Patients aged 6 – 60 months hospitalized due to pneumonia and treated as inpatients at the Respiratory Departments 1 and 2, Children's Hospital 2, with their primary caregivers' consent to participate in the study. Each patient is only enrolled in the study during their first hospitalization for this illness episode, excluding those who are readmitted or transferred back to the department.

Exclusion Criteria

Research forms lacking ≥ 50% of the information or missing data on the child’s weight, patients who were previously admitted to the Intensive Care Unit before being transferred to the Respiratory Department or those who were initially treated at lower-level hospitals before being transferred to Children's Hospital 2, patients were readmitted or transferred back to the department, patients transferred to other departments or ICU.

Sample Size

The sample size was calculated using the formula: 

$$n = \frac{Z_{1-\alpha/2}^2 p (1-p)}{d^2}$$

Where:
- $n$: Minimum sample size for the study
- $\alpha$: Type I error, chosen as $\alpha = 0.05$
- $Z_{1-\alpha/2}$: Standard normal distribution value with 95% confidence $\Rightarrow Z_{1-\alpha/2} = 1.96$
- $d$: Margin of error, $d=0.07$
- $p$: Estimated proportion of children experiencing weight loss upon admission, $p=70.1\%$ (based on the study by Hwang et al. at Korean).

With a 10% expected drop-out rate, $n=182$

Data Collection

Children's weights were measured daily from admission to discharge. Medical records were reviewed to assess the treatment response of the children.

Weight change after 3 days, 7 days, and at discharge was determined by the difference between the weight at admission and the weight on the 3rd day, 7th day, and at discharge, respectively.

Weight Loss was calculated based on the formula:

$$\text{Weight Loss (\%)} = \frac{\text{Weight at admission} - \text{Current Weight}}{\text{Weight at admission}} \times 100$$

Treatment Response: Based on the level of treatment response, categorized into two values:

- Poor: Increased oxygen requirement or escalated/added antibiotics
- Good: Maintained or reduced oxygen/antibiotics
Statistical analysis
Data was entered using EpiDATA software. Data processing and analysis were conducted using Stata 17.0 software. Qualitative variables will be described using frequency and percentage. Quantitative variables will be described using mean and standard deviation; if the distribution is not normal, they will be described using median and interquartile range. Risk ratio (RR) was calculated with 95 confidence interval (CI).

III. RESULTS
The study was conducted on 208 children, with 127 males (61.1%) and 81 females (38.9%). Among them, 59 children were 6-12 months old (28.4%), 92 children were 13-24 months old (44.2%), and 57 children were 25-60 months old (27.4%). During this treatment period, the majority of the children did not require intensive care or emergency services (88.0%), and the treatment prognosis was good (84.6%). The median length of hospital stay for the children was 7 days, with an interquartile range of 5-10 days.

Table 1 shows that after 3 days of hospitalization, 27.6% of the children experienced weight loss. After 7 days, 38.1% of the children had weight loss, and after hospitalization at discharge, the percentage of children with weight loss was 38.0%. As shown in the Table 2, the children who experienced weight loss ≥ 5% after 7 days of hospitalization had a tend of longer length of hospital stay compared to those with weight loss < 5% (p=0.058).

Table 3 shows that treatment response in children with weight loss < 5% after 3 days and during hospitalization was better compared to children with weight loss ≥ 5% (p < 0.05). Children with weight loss < 5% after 7 days had a tend of better treatment response compared to those with weight loss ≥ 5%.

IV. DISCUSSION

Relationship between weight loss ≥ 5% after 3 days of hospitalization and length of hospital stay

Weight loss during hospitalization indicates that the child is not receiving adequate nutrition or is experiencing significant fluid loss due to vomiting, diarrhea, etc. Prolonged weight loss can lead to malnutrition in hospitalized children. A study by K. Huysentruyt et al. conducted on 379 children in Belgium found that malnourished children had longer hospital stays [4]. The study identified a statistically significant relationship between weight loss after 3 days of hospitalization and the length of hospital stay (p = 0.043). Specifically, children who experienced weight loss ≥ 5% after 3 days of hospitalization had
longer hospital stays compared to those with weight loss < 5%. It is possible that if weight loss is not addressed within the first 3 days of hospitalization, it could continue and negatively impact the treatment, thereby prolonging the hospital stay.

**Relationship between weight loss ≥ 5% after hospitalization and length of hospital stay**

Excessive weight loss can hinder the treatment process and prolong the length of hospital stay. The study found a statistically significant relationship between weight loss during hospitalization and the length of hospital stay (p < 0.001). Specifically, children who experienced weight loss ≥ 5% had longer hospital stays compared to those with weight loss < 5%. This finding is consistent with the study by G. A. Rocha on 203 children under 5 years old hospitalized in Fortaleza, Brazil, which also found that prolonged hospitalization was associated with weight loss during the hospital stay (p < 0.001) [5].

**Relationship between weight loss ≥ 5% after 3 days of hospitalization and treatment response**

The study found a statistically significant relationship between weight loss after 3 days of hospitalization and the treatment response in children (p = 0.025). Weight loss after 3 days of hospitalization could be due to symptoms of the illness, dehydration (loss through sweat, vomiting, diarrhea, etc.), and loss of appetite. This is a warning sign that early intervention is needed to prevent malnutrition and complications, ensuring that the treatment process is not adversely affected. Improving the nutritional status of these children ensures they receive adequate nutrients, which enhances their immune response, speeds up recovery, and results in a better treatment response. Parental knowledge on caring for children under 5 years old with pneumonia in Vietnam still has many areas for improvement, especially regarding nutritional care [6,7].

**Relationship between weight loss ≥ 5% during hospitalization and treatment response**

There is a statistically significant relationship between weight loss ≥ 5% after hospitalization and treatment response in children (p = 0.001). Weight loss can lead to a deficiency in essential nutrients, weakening the immune system and resulting in poorer treatment response compared to children who do
not experience weight loss. This increases the risk of complications, making the illness more severe and difficult to treat, requiring a longer recovery period. However, parents may not fully understand how to provide proper nutritional care for their hospitalized children to prevent weight loss. According to a study by Trần Đỗ Hùng and Nguyễn Thị Đại Trang (2013) on 100 mothers of children aged 2-5 years with pneumonia at the General Internal Medicine Department, Children's Hospital Cần Thơ, most children were fed, drank, or nursed as usual (46%), while some mothers believed their children should eat and drink less (24%)[6]. Another study by Trần Thị Ngọc Bình and Phạm Ngọc Toàn (2022) on 300 caregivers of children with pneumonia aged 1 month to 5 years treated at Department C, National Children's Hospital (Hanoi) found that only 18% of caregivers practiced incorrect nutritional care for the children.

Over time, nutritional care for children has become more of a focus, and caregivers have gained more knowledge on how to care for children during illness [7].

**Limitations**

The study only accounted for the weight loss during hospitalization of pneumonia patients based on the change in their current weight compared to the time of admission. It did not account for the change in weight compared to the actual weight of the pediatric patients before illness. Furthermore, patients who were previously admitted to the Intensive Care Unit before being transferred to the Respiratory Department or those who were initially treated at lower-level hospitals before being transferred to Children's Hospital 2 had to be excluded, which means the study did not represent all pediatric pneumonia patients.

**V. CONCLUSION**

There is a relationship between weight loss ≥ 5% after 3 days and during hospitalization with the length of hospital stay and treatment response. Children who experienced weight loss ≥ 5% had longer hospital stays and poorer treatment responses compared to those with weight loss < 5% after 3 days and after hospitalization. Regularly monitoring the child’s weight during treatment to prevent excessive weight loss, which can negatively impact the treatment process and prolong hospital stay.
